20 Abstract

26 *Toxoplasma gondii* (*T. gondii*), an intracellular parasite, utilizes a variety of rho-try proteins
27 (ROPs) to facilitate invasion and interactions with host cells. Among these ROPs, Rho-try Protein
28 13 (ROP13) stands out for its expression in both bradyzoite and tachyzoite forms of *T. gondii* and
29 its ability to engage with various host cytoplasmic compartments. In this bioinformatics study, we
30 employed a range of tools to predict the fundamental characteristics of the ROP13 protein. Our
31 analysis revealed that the ROP13 protein consists of 400 amino acid residues with an average
32 molecular weight (MW) of 44,714.15 Daltons. The grand average of hydropathicity (GRAVY)
33 was determined to be -0.311, indicating the protein's hydrophilic nature, while the aliphatic index
34 scored 84.40, highlighting its hydrophobic properties. Furthermore, we identified 43 post-
35 translationally modified sites within the ROP13 sequence. When examining the secondary
36 structure, the ROP13 protein was predicted to have a composition of 40% alpha-helix, 9.25%
37 extended strand, and 50.75% random coil using the GOR4 method, suggesting a diverse structural
38 organization that may contribute to its functional versatility. Additionally, our analysis identified
39 several potential B- and T-cell epitopes within the ROP13 sequence, indicating regions that could
40 be targeted for immune responses.

41 Overall, the bioinformatics analysis of ROP13 provides valuable insights into its structural,
42 immunogenic, and antigenic properties, highlighting its potential as a target for vaccine
43 development against toxoplasmosis. By leveraging the predicted characteristics of ROP13,
44 researchers can explore various vaccine strategies to enhance host immunity and combat *T. gondii*
45 infection effectively. Continued investigation into the molecular mechanisms underlying ROP13's
46 interactions with host cells will further elucidate its role in toxoplasmosis pathogenesis and guide
47 the development of innovative approaches to mitigate this prevalent parasitic disease.

48 **Keywords:** *Toxoplasma gondii*, Rho-try protein 13, *In silico*

49

50 1.1. Introduction

51 *Toxoplasma gondii* is a widely distributed protozoan parasite posing a significant public health
52 concern, with an estimated one-third of the global population exposed to this parasite (1,2).

53 The life stages of *T. gondii* consist of a sexual phase and an asexual phase, which exclusively occur
54 in the feline species (definitive hosts) and any warm-blooded animal (intermediate hosts),
55 respectively (3–5). Oocysts, shed through the feces of definitive hosts, serve as the infectious stage

of *T. gondii*. Environmental, soil, and water contamination are the primary sources of infection (6). Accordingly, humans acquire the infection via contaminated drinking water or food, consumption of raw/undercooked meats containing latent cysts, vertical transmission, organ transplantation, and blood transfusion (6,7).

The clinical characteristics of toxoplasmosis are influenced by various factors, including the genotype of the protozoan and host-related characteristics such as age, gender, occupation, genetics, diet, immunological status, cultural behaviors, and contact with infected cats (8–10).

In immunocompetent individuals, *T. gondii* generally causes mild clinical manifestations, such as flulike symptoms, while in some humans with weak immune status (patients with HIV/AIDS, seronegative pregnant women, and organ transplant recipients), *T. gondii* infections cause serious disease, such as encephalitis, mental retardation, vision disorders, hydrocephalus, cerebral calcification, poor coordination, or may lead to death if not treated (11,12). *T. gondii* infection can lead frequent abortions, stillbirths, the birth of debilitated animals, and fetal death in some domestic animals, particularly sheep and goats. These outcomes result in significant economic disadvantages in animal husbandry settings and veterinary-related industries (13).

Toxoplasmosis is typically treated with chemotherapy that includes anti-malarial and antibacterial medications, which are the recommended drugs for managing the disease. Nevertheless, these agents have not been completely successful yet, and can have harmful side effects such as teratogenic traits, hypersensitivity, damaging some tissues, significant toxicity, potential parasite resistance as well as bone marrow suppression (14,15).

Since antiparasitic drugs have some limitations and are unable to eradicate bradyzoites in tissue cysts, discovering and design of secure and impressive vaccines are needed, particularly in humans and livestock animals. One of the significant challenges facing scientists in addressing *T. gondii* infection is the development of a useful and effective vaccine. To address this challenge, various immunization approaches with different formulations have been explored for toxoplasmosis. Recent vaccine development trials aimed at preventing *T. gondii* infection have primarily focused on antigens found on the parasite's major surface (SAGs), as well as proteins from micronemes (MICs), rhoptries (ROPs), and dense granules (GRAs) (16–19).

Among these different antigens, ROP protein family is a hoping vaccine candidate due to strong antigenicity and immunogenicity, as well as its ability to induce substantial immune responses (20,21). Several studies have assessed the efficacy of ROP antigens using different vaccine

platforms such as recombinant protein or DNA vaccines on the animal models in order to obtain favorable and promising results (18–21). As an excretory-secretory protein of *Toxoplasma gondii*, ROP13 has the ability to moderate immune response and therefore it shows great promise for application in immunization approaches against the infection (21). Furthermore, this protein exhibits strong immunogenicity similar to other ROPs and plays a crucial role in pathogenicity and survival within host cells (21–24).

Using *in silico* tools to predict vaccine targets is highly valuable as it enhances our understanding of these targets and allows for their rapid selection with careful consideration (25,26). Bioinformatics are the most successful prediction method for identifying effective epitopes and developing vaccine (25). These novel techniques are highly beneficial for analyzing proteins and assessing their structural, functional, immunogenic, biological, and biochemical characteristics as antigens (19,26). Therefore, the present study was designed aiming at identifying the essential biochemical characteristics and immunogenic epitopes of the ROP13 protein by utilizing various bioinformatics online servers.

1.1

1.2 2. Methods

1.3 2.1. Retrieval and initial assessment of the protein sequence

1.4 Initially, the amino acid sequence of ROP13 was obtained from the National Center for
1.5 Biotechnology Information (NCBI) website (<https://www.ncbi.nlm.nih.gov/protein/>) in FASTA
1.6 format.

1.7

1.8 2.2. Analysis of the physicochemical parameters of ROP13

1.9 The ExPASy ProtParam (<https://web.expasy.org/protparam/>) was utilized to assess the various
1.10 physicochemical characteristics of ROP13, including amino acid composition, theoretical
1.11 isoelectric point (pI), molecular weight (MW), total number of positively and negatively charged
1.12 residues, extinction coefficients, instability index, aliphatic index, grand average of hydropathicity
1.13 (GRAVY), and *in vitro* and *in vivo* half-life (27).

1.14

1.15 2.3. Projecting the post-translational modification (PTM) sites on ROP13

1.16 The online tools of NetPhos 3.1 (<http://www.cbs.dtu.dk/services/NetPhos/>) and CSS-Palm

117 ((<http://csspalm.biocuckoo.org/online.php>) were used to determine the phosphorylation and
118 acylation regions of the ROP13 protein, respectively (25).

119

120 **2.4. The transmembrane domains and subcellular position of ROP13**

121 The potential transmembrane regions (TMs) of ROP13 were evaluated using the TMHMM 2.0
122 (<http://www.cbs.dtu.dk/services/TMHMM-2.0/>). Additionally, the subcellular position of the
123 protein was projected using the PSORT II (<http://psort.hgc.jp/form2.html>) (25).

124

125 **2.5. The secondary and tertiary structure prediction**

126 The secondary structure of ROP13 was anticipated using the Garnier-Osguthorpe-Robson (GOR)
127 method through the online server ([https://npsa-
128 prabi.ibcp.fr/cgi-bin/npsa_automat.pl?page=npsa_gor4.html](https://npsa-prabi.ibcp.fr/cgi-bin/npsa_automat.pl?page=npsa_gor4.html)) (28). Afterward, the three-
129 dimensional (3D) models of ROP13 sequence were generated using the SWISS-MODEL program,
130 using a homology modeling approach (<https://swissmodel.expasy.org/>) (25,29).

131

132 **2.6. Refinement and confirmation of the 3D modeled structure**

133 The precision and quality of the generated models were determined through Ramachandran plot
134 using SWISS-MODEL (<https://saves.mbi.ucla.edu/>) (30).

135

136 **2.7. B-cell epitopes projection**

137 To predict B-cell epitopes, the amino acid sequence of the ROP13 protein (accession no.
138 AFH54221.1) was utilized. The ABCpred online server (<http://crdd.osdd.net/raghava/abcpred/>)
139 was employed with a threshold of 0.75% to identify linear B-cell epitopes within the antigen
140 sequence (31). To project the B-cell epitope, we utilized the Bcepred tool, which determines
141 continuous B-cell epitopes based on physicochemical properties such as accessibility, polarity,
142 hydrophilicity, turns, exposed surface, flexibility, and antigenic propensity was used
143 (http://crdd.osdd.net/raghava/bcepred/bcepred_submission.html) (32).

144 Besides, the IEDB tool of the Immune Epitope Database (<http://tools.iedb.org/bcell/>) was
145 employed to evaluate epitopes according to average flexibility, hydrophobicity, surface
146 accessibility, antigenicity, alpha-helix and beta-turn. Eventually, conformational B-cell epitopes
147 were appraised using ElliPro (<http://tools.iedb.org/elliopro/>) from the 3D epitope structure protein

148 data bank file by default parameters, comprising 0.5 min-score and 6 Å max distance. This server
149 is able to predict the epitopes based on their protusion index (PI) values to estimate the protein
150 shape, residual PI, and adjacent cluster residues (33).

151

152 **2.8. MHC-I and MHC-II binding epitopes projection**

153 The Immune Epitope Database (IEDB) was used to assess the half maximal inhibitory
154 concentration (IC₅₀) of peptides derived from ROP13, which exhibit affinity to both major
155 histocompatibility complex (MHC) class I and class II molecules. This was done using the
156 recommended method provided by IEDB, accessible at the following links: for MHC class I
157 molecules (<http://tools.iedb.org/mhci/>) and for MHC class II molecules
158 (<http://tools.immuneepitope.org/mhcii>).

159 The MHC-I epitopes, each consisting of ten amino acids, were predicted using the mouse alleles
160 H2-Ld, H2-Db, H2-Dd, H2-Kb, H2-Kd, and H2-Kk. For MHC-II epitope prediction, which
161 involved 15 amino acids, the mouse alleles H2-IAb, H2-IAd, and H2-IEd were employed. The
162 predictions were sorted by percentile rank (34,35).

163

164 **2.9. Cytotoxic T lymphocyte (CTL) epitopes prediction**

165 Identification of cytotoxic T-cell epitopes was accomplished using the CTLpred tool with
166 performance accuracy of 75.8% (<http://www.imtech.res.in/raghava/ctlpred/index.html>). The
167 prediction was done according to a consensus approach, previously described. The default
168 parameters for the prediction were support vector machine of 0.36 and artificial neural network of
169 0.51 (36).

170

171 **2.10. Evaluation of antigen probability, allergenicity, and solubility**

172 The full ROP13 protein antigenicity was assessed initially with ANTI-GENpro
173 (<http://scratch.proteomics.ics.uci.edu/>) (37), and finally with VaxiJen v. 2.0 (<http://www.ddg-pharmfac.net/vaxijen/>) (38) web bases servers.

174 VaxiJen is used to predict conserved antigenic regions and it employs a novel alignment-free
175 approach based on auto-cross covariance (ACC), which evaluates changes in peptide sequences to
176 generate comparable vectors of primary amino acid features. The precision ranges between 70%

177

178 and 89%, based on the target organism ([http://www. Ddg](http://www.Ddg)
179 [pharmfac.net/vaxijen/VaxiJen/VaxiJen_help.html](http://www.Ddgpharmfac.net/vaxijen/VaxiJen/VaxiJen_help.html)).

180 Furthermore, the allergenic profile of ROP13 was projected using the AlgPred
181 (<http://www.imtech.res.in/raghava/algpred/>) (39) with a hybrid methodology combining SVMc,
182 IgE epitope prediction, ARPs BLAST, and MAST. AlgPred can project epitopes with 85%
183 accuracy by comparing the identified epitope with protein regions, using a threshold of -0.4. The
184 solubility of ROP13 was projected using the SOLpro server (<http://scratch.proteomics.ics.uci.edu/>)
185 (40).

186

187 **2.11. Immune simulation**

188 The C-ImmSim was employed to predict the virtual immunological simulation process that was
189 provoked by TgROP13 (<https://150.146.2.1/C-IMMSIM/index.php?page=1>). It was set for three
190 inoculation doses of TgROP13 at four-week intervals with time points of 1, 84, and 168. Other
191 settings for this computer-aided simulation included simulation volume 10, simulation steps 1050,
192 and random seed 12345 (42).

193

194 **3. Results**

195 **3.1. Gene and overall features of ROP13**

196 The amino acid sequence of the ROP13 protein, acquired from NCBI in FASTA format (accession
197 no. AFH54221.1).

198 According to ProtParam, the ROP13 protein consists of 400 amino acid residues with a predicted
199 pI of 9.38 and a molecular weight of 44714.15 D. The ROP13 sequence contains 45 negatively
200 charged residues (Asp + Glu) and 56 positively charged residues (Arg + Lys).

201 The extinction coefficient was measured to be 20440 M⁻¹ cm⁻¹ in water at 280 nm.

202 The estimated half-life of ROP13 was 30 hours in mammalian reticulocytes *in vitro*, over 20 hours
203 in yeast *in vivo*, and over 10 hours in *Escherichia coli in vivo*.

2.4 Moreover, the instability index (II) of this protein indicates its unstable nature, with a score of
 2.5 61.30. In addition, the GRAVY and aliphatic index were calculated to be -0.311 and 84.40,
 2.6 respectively.

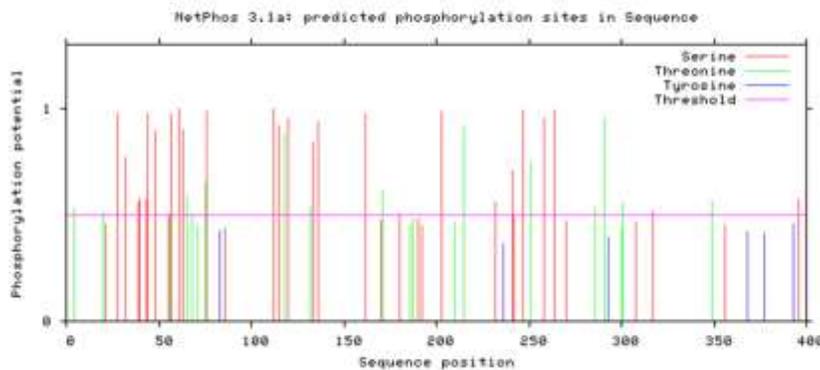

2.7

2.8 3.2. PTM sites projection on ROP13

2.9 The results revealed that the ROP13 protein contains 41 phosphorylation sites (27 Ser, 14 Thr, and
 2.10 0 Tyr) as shown in Figure 1A and B, along with 2 acylation sites listed in Table 1, indicating that
 2.11 there are a total of 43 PTM sites within our sequence.

۲۳۷ **3.3. Forecasting transmembrane regions and subcellular localization of ROP13**

۲۳۸ According to TMHMM results, there observed one transmembrane domain in ROP13 sequence
 ۲۳۹ (Fig. 2). In addition, using the PSORT II program, ROP13 subcellular site was determined as
 ۲۴۰ follows: 33.3% plasma membrane, 22.2% endoplasmic reticulum, 33.3% Golgi, and 11.1%
 ۲۴۱ extracellular, including cell wall.

3.4. Assessment of secondary and tertiary structure

206 The GOR4 analysis showed that the secondary structure of the ROP13 protein consists of 400
 207 amino acids and comprises 40% alpha helix (H) (160/400), 50.75% random coil (203/400), and
 208 9.25% extended strand (37/400) (Fig. 3). The SWISS-MODEL findings are entirely depicted in

299 The graphical prediction of continuous B-cell epitopes for ROP13 was conducted using the
 300 following threshold values for different parameters: Bepipred linear (0.502), hydrophilicity
 301 (1.471), flexibility (1.000), antigenicity (1.038), beta-turn (0.966), and surface accessibility
 302 (1.000) (Fig. 6). Fourteen discontinuous epitopes of B-cell were forecasted employing the ElliPro
 303 server (Table 4).

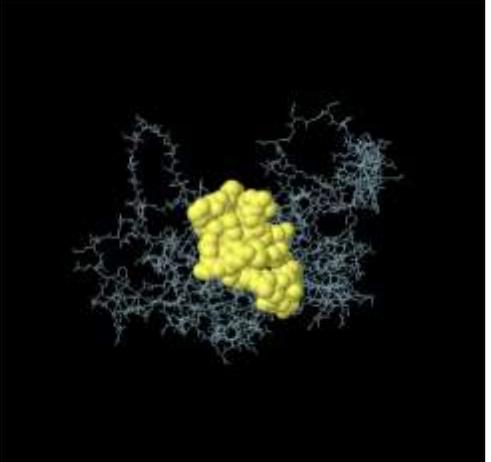

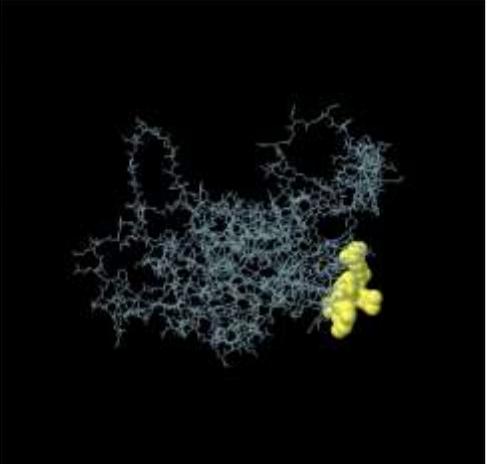

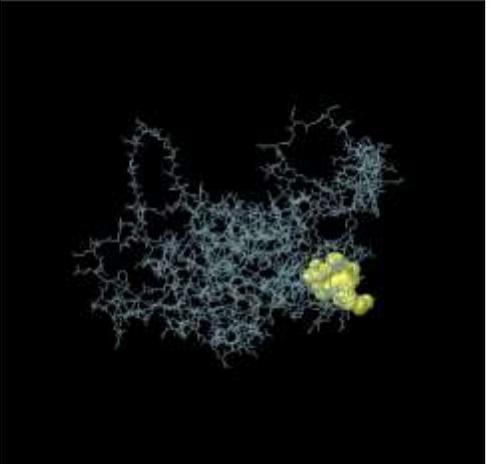

304 **Table 4.** Conformational B cell epitopes of TgROP13 protein predicted by ElliPro server.

Fig. 6. Linear B-cell epitopes of ROP13 protein sequence predicted by ProtScale server (<https://web.expasy.org/protscale/>), based on percent of accessible residues(A), Beta-turn (B), Antigenicity (C), Bepipred linear (D), Flexibility (E) and Hydrophilicity (F). The horizontal line indicates the threshold or the average score. Yellow colors (above the threshold) indicate favorable regions related to the properties of interest. Green color (below the threshold) indicates the unfavorable regions related to the properties of interest.

314 **3.7. MHC-I and MHC-II binding epitopes projection**

315 The T-cell epitopes with the lowest IC₅₀ values (or percentile ranks) were selected. The minimum
 316 percentile scores of each MHC allele for ROP13 are presented in Table 5 and 6.

317

337 ^aCTLpred, available online at <http://www.imtech.res.in/raghava/ctlpred/index.html>. ^bNine amino acids for analysis
 338 were used. ^cThe default artificial neural network (ANN) and support vector machine (SVM) cut-off scores were set
 339 0.51 and 0.36, respectively.

340 3.9. Antigenicity, allergenicity, and solubility assessment

341 The antigenicity scores of ROP13 were calculated as 0.821125 and 0.5796 using ANTIGEN-pro
 342 and VaxiJen v.2.0, respectively. A threshold value of 0.5 was considered for both models.
 343

344 The findings of the AlgPred server using the hybrid approach demonstrated that the ROP13 protein
345 is not allergen.

346 The ROP13 protein solubility after overexpression in *E. coli* was calculated at 0.7847.

347 **4. Discussion**

348 Toxoplasmosis is now widely remained as one of the main threat to human society and livestock
349 industry that lacks a global solution (6,7,13). So far, no vaccine or appropriate treatment is
350 available to prevent and control of this infectious disease. Furthermore, the existing drugs are not
351 entirely satisfactory and can induce adverse side effects in patients (7,14). Hence, the quest to
352 develop an effective and safe vaccine specifically targeting toxoplasmosis has been a key area of
353 research for scientists worldwide (43).

354 Nevertheless, designing successful vaccines with conventional methods is expensive, tedious, and
355 takes considerable time. *In silico* is the most successful technology to the identification of accurate
356 biomarkers to guide treatment selection that can significantly reduce both time and cost of
357 diagnosis (44). Research has demonstrated that the ROP family has a critical impact on invasion
358 of *T. gondii* and its interaction with host cells (20,21). The ROP13 protein has the ability to enter
359 the cytoplasm of host cells, demonstrating strong immunogenicity and pathogenicity (22). Current
360 investigation was performed to analyze and compare the different aspects of the ROP13 protein
361 using bioinformatics techniques and online servers to design a suitable toxoplasmosis vaccine. The
362 present research employed multiple bioinformatic tools to assess the diverse features of ROP13. It
363 is indicated that peptides with MW of < 5–10 KDa are regarded as a poor immunogenic (45).
364 Herein, it has been found that the amino acid sequence of the ROP13 protein comprises 400
365 residues and an average MW of 44,714.15 D, suggesting a good antigenic nature.

366 Our analysis showed that the aliphatic index and GRAVY score of the ROP13 sequence were
367 calculated as 84.40 and -0.311, respectively. A high aliphatic index shows that the target protein
368 is stable over a broad spectrum of temperatures. The negative or low GRAVY score highlights that
369 the peptide has better interaction with surrounding water molecules. It is widely recognized that
370 ROPs contain an N-terminal signal sequence and a C-terminal hydrophobic sequence, which is
371 believed to include a transmembrane region (46).

372 In this study, we observed that there was only one transmembrane region for ROP13 gene
373 sequence. Studies have indicated that PTM sites serve as a set of enzymatic functions capable of
374 modulating the function, structure, and stability of proteins (47). Accordingly, we identified
375 acylation and phosphorylation sites on the ROP13 protein. Our findings revealed a total of 43 PTM
376 sites (2 acylation and 41 phosphorylation positions) within the sequence. These sites suggest the
377 potential modulation of protein function, which could influence its activity.

378 It is well established that the secondary structure of proteins depends on the hydrogen bond pattern
379 between amino hydrogen atoms and carboxyl oxygen atoms in a polypeptide chain, with alpha
380 helices and beta sheets being the commonest structure (48). Proteins play a crucial role in the body
381 due to their three-dimensional shape. Understanding the correlation between protein structure and
382 function is essential. Therefore, determining the tertiary structure of proteins is a key step in
383 unraveling their functional properties (47). Our investigation into the secondary structure of
384 ROP13 revealed that it contains 40% alpha helix, 9.25% extended strand, and 50.75% random coil.
385 The plot of Ramachandran revealed that 91.8% of amino acid residues were located in the ideal
386 regions, with 7.6% and 0.6% found in the allowed and disallowed regions of the plot, respectively.

387 Several studies have demonstrated that immunization against *T. gondii* infection is conferred
388 through acquired immune responses, including humoral and cellular immunity, as well as
389 regulatory cytokines (48–52). Specific IgG antibodies, acting as anti-*Toxoplasma* antibodies,
390 effectively control and limit parasite growth (50). They interfere parasite replication by limiting
391 its adhesion to surface receptors on host cells and inhibiting with the functions of parasite proteins
392 (50,51). They also stimulate macrophage phagocytosis, which enhances the body's immune
393 response against intracellular parasite infections (51,52). Additionally, the secretion of interferon-
394 γ (IFN- γ) by CD4+ and CD8+ T-cells is a critical indicator of cellular response generation. This
395 response is essential for preventing the reactivation of bradyzoites within the host tissue cyst
396 (51,52). In addition, epitope identification is helpful as it directly induce a robust immunity to
397 properly control the parasite in vaccine design researches (47). *In silico* B-cell epitope mapping
398 enables a better understanding of epitopes that are essential with regards to the interactions that
399 happen between antibodies and pathogens.

400 The continuous B-cell epitope prediction results revealed that the ROP13 protein contains positive
401 epitopes with acceptable indexes, as determined using the Bcepred online server. Subsequently,
402 we utilized this server to identify B-cell epitopes based on various physicochemical characteristics
403 including accessibility, hydrophilicity, flexibility/mobility, exposed surface, polarity, turns, or a
404 combination of these properties (19).

405 The lower IC₅₀ values indicate a higher affinity for MHC binding, indicating an appropriate T-cell
406 epitope. The analysis of IC₅₀ values of peptides from the IEDB output indicated that the T-cell
407 epitopes on ROP13 can strongly bind to MHC class I and class II molecules.

408 **5. Conclusion**

409 This research provides insights into the potential role of the ROP13 protein in combating *T. gondii*
410 infection, supported by bioinformatics analyses. However, further experimental validation is
411 needed to definitively assess its effectiveness. The goal of such studies is to completely
412 comprehend the role of the ROP13 proteins in preventing *T. gondii* infection, which requires
413 conducting comprehensive experimental studies and finding more information.

414 **Declarations**

415 **Acknowledgement**

416 We sincerely thank personnel from the Medical Microbiology Research Center, Qazvin University
417 of Medical Sciences, Qazvin, Iran and Jahrom University of Medical Sciences, Jahrom, Iran.

418 **Author contribution**

419 MB, AVE, MF and LZ designed the study. MB, MGC, AKS, DD, and MP searched for primary
420 publications, screened and appraised of data. MB, LZ and AVE wrote the study manuscript. MB,
421 KHN and AVE: edited the manuscript. DD, MB, AVE and MF contributed to data analysis. All
422 authors read the manuscript and participated in the preparation of the final version of the
423 manuscript.

424 **Competing interests**

٤٢٥ The authors declared no potential conflicts of interest concerning the research or authorship.

٤٢٦ **Funding**

٤٢٧ This work was supported by the Medical Microbiology Research Center, Qazvin University of
٤٢٨ Medical Sciences, Qazvin, Iran (contract no. IR.QUMS.REC.1400.481). The funder of the study
٤٢٩ had no role in study design, data collection, data analysis, data interpretation, or writing of the
٤٣٠ report.

٤٣١ **Ethics approval and consent to participate**

٤٣٢ The current study was performed by approval of the ethics committee of Qazvin Medical
٤٣٣ University with approval number IR.QUMS.REC.1400.481. The research protocol was approved
٤٣٤ by the Research Ethics Committee at the Qazvin Medical University, Iran.
